

Filtering with misspecification in the Lorenz-63 System

$$\frac{dx}{dt} = \sigma(y - x) , \quad \frac{dy}{dt} = x(\rho - z) - y , \quad \frac{dz}{dt} = xy - \beta z$$

Steps to check misspecification of filter

- 1) Simulate Lorenz system with several different parameters and noise
- 2) Fit a filter (possibly several with different settings) to the data
- 3) Compare the fit to the system as well as forecasting performance at different forecasting lengths
- 4) Repeat for various training lengths
- 5) Repeat process many times and average
